HID Over GATT Profile

***Bluetooth*® Profile Specification**

- ~~**Revision:** V10r00~~
- **Version:** v1.1
- **Version Date:** ~~2011-12-27~~2025-08-05
- ~~**Group** **Prepared By:** HID WG~~Human Interface Device Working Group
- ~~**Feedback Email:** hid-main@bluetooth.org~~

This document is provided as a courtesy to help readers identify changes between two versions of a Bluetooth specification. When implementing specifications, use the adopted versions located at www.bluetooth.com.

Abstract:

This profile defines how a device with Bluetooth® low energy wireless communications can support Human Interface Device (HID) services over the Bluetooth low energy protocol stack using the Generic Attribute Profile and LE Isochronous Channels.

~~Revision~~Version History

~~Revision~~Version Number	Date (yyyy-mm-dd)	Comments
~~D09r01~~	~~2011-06-30~~	~~First Draft of LE HID Profile~~
~~D09r02~~	~~2011-07-05~~	~~Review comments from Alain Michaud and Jacques Chassot~~
~~D09r03~~	~~2011-07-08~~	~~Updated the review comments, HID Flags and added Appendix A~~
~~D09r04~~	~~2011-07-15~~	~~Revised section 0 to clarify device-initiated and host-initiated connection establishment~~
~~D09r05~~	~~2011-07-15~~	~~Sandeep Kamath updated text in sections 5.1.2 and 5.2.6, fixed Idle Connection Timeout references~~
~~D09r06~~	~~2011-07-21~~	~~Updated at HID WG F2F, Malmö~~
~~D09r07~~	~~2011-08-04~~	~~Changes for Option 1a~~
~~D09r08~~	~~2011-08-09~~	~~Added section 4.3.1.5~~
~~D09r09~~	~~2011-08-10~~	~~Added review comments and renamed "Flags" to "Information"~~
~~D09r10~~	~~2011-08-11~~	~~Added review comments~~
~~D09r11~~	~~2011-08-11~~	~~Added more comments~~
~~D09r12~~	~~2011-08-12~~	~~Updates from HID WG CC, 2011-08-11~~
~~D09r13~~	~~2011-08-17~~	~~Removed addressed comments, added a few editorial changes~~
~~D09r14~~	~~2011-08-17~~	~~Added comments from Chris Church and Mike Tsai~~
~~D09r15~~	~~2011-08-19~~	~~Resolved comments~~
~~D09r16~~	~~2011-08-22~~	~~Removed soft/hard reset commands~~
~~D09r17~~	~~2011-08-26~~	~~Updated section 5.1.3, removed addressed comments~~
~~D09r18~~	~~2011-08-29~~	~~Revision Revoked~~
~~D09r19~~	~~2011-09-05~~	~~Clean version~~
~~D09r20~~	~~2011-09-06~~	~~Changed Boot Mode only Hosts~~
~~D09r21~~	~~2011-09-07~~	~~Added more details on Boot Mode only Hosts~~
~~D09r22~~	~~2011-09-08~~	~~Added recommendation for DIS C1 values.~~
~~D09r23~~	~~2011-09-10~~	~~Added review comments~~

~~Revision~~Version Number	Date (yyyy-mm-dd)	Comments
~~D09r24~~	~~2011-09-12~~	~~Accepted review comments and changed Tables 4-1 and 4-2 to accommodate clarified requirements. Added to sections 3.1 through 3.4 to clarify additional security requirements beyond Service Specs~~
~~D09r25~~	~~2001-09-13~~	~~Changes to accommodate HID Boot Report Mapping as a characteristic, including updating Tables 4-1 and Table 4-2, adding new characteristic and GATT sub-proc. Rationalized conditionals in Tables 4-1 and 4-2. Updated section 4.2 updated Security Considerations in s6.1.~~
~~D09r26~~	~~2011-09-13~~	~~Updated table 6-1. Updated references section~~
~~D09r27~~	~~2011-09-14~~	~~Added new subsections to 3.1, 3.2, 3.3, 3.4 to define Service Types & reformatted subsections~~
~~D09r28~~	~~2011-09-14~~	~~Addressed review comments, changed all instances of Report Mode to Report Protocol Mode and all instances of Boot Mode to Boot Protocol Mode. Inserted table of Figures and List of Tables. Changed section 4.2.2.1 to separate Service & Characteristic discovery for Boot Protocol Mode Hosts. Issued clean version~~
~~D09r29~~	~~2011-09-16~~	~~Updates from HID WG CC 2011-09-15~~
~~D09r30~~	~~2011-09-16~~	~~Formatting edits, changed HID Report to HID Control Point in section 4.8~~
~~D09r31~~	~~2011-09-17~~	~~Updated section 4.8 for Get Protocol Mode~~
~~D09r32~~	~~2011-09-19~~	~~Addressed review comments from Jacques Chassot~~
~~D09r33~~	~~2011-09-20~~	~~Corrected references column in Table 4-1~~
~~D09r34~~	~~2011-09-26~~	~~Renamed to HID over GATT~~
~~D09r35~~	~~2011-09-29~~	~~Reverted some low energy deletions, added HID State, addressed Tim and Randy's comments.~~
~~D09r36~~	~~2011-09-29~~	~~Added HID Protocol Mode, removed get/set protocol from HID Control Point. Comments addressed from HID WG CC~~
~~D09r37~~	~~2011-10-09~~	~~Updates from the Budapest F2F~~
~~D09r38~~	~~2011-10-15~~	~~Added details on Translation Layer, Report Instance characteristic descriptor and External Report Reference characteristic descriptor.~~
~~D09r39~~	~~2011-10-15~~	~~Updated following redesign of HID Service after BARB review. Removed Report Reference characteristic descriptor from Report Map characteristic and into Report (or non-HID Service characteristics). Added External Report Reference characteristic descriptor. Multiple HID Services~~

~~Revision~~Version Number	Date (yyyy-mm-dd)	Comments
		~~allowed. Mandated including external services with characteristics described in Report Map.~~
~~D09r40~~	~~2011-10-25~~	~~Updated to match HID Service r38 (removed Boot Report Reference characteristic, added Boot Keyboard Input Report, Boot Keyboard Output Report, and Boot Mouse Input Report).~~
~~D09r41~~	~~2011-11-02~~	~~Addressed BARB review comments, reinstated mandatory HID service discovery for Boot Mode Hosts, and optional DIS and Battery service discovery. Added optional characteristic discovery for Boot Mode hosts. Updated section 5.1.6 to refer to Scan Parameters Profile/Service. Added behavior sections for Boot mode characteristics. Added exchange MTU sub-procedure requirement for Report Hosts. Added information sharing for bonding and service changed requirement for HID Hosts.~~
~~D09r42~~	~~2011-11-08~~	~~Addressed BARB review comments. Removed optional support of Report and non-HID Service characteristic in Table 4-2.~~
~~D10r00~~	~~2011-11-23~~	~~Added clarification in Section 3.1.1 regarding external service characteristics' mandatory requirements for characteristic properties. Submitted as v1.0 voting object to BARB~~
~~D10r01~~	~~2011-12-07~~	~~Added note in Section 4.5.3 regarding multiple Battery Service instances & use of the characteristic presentation format descriptor. Resubmitted as v1.0~~
V10r00	2011-12-27	Adopted by the Bluetooth SIG Board of Directors
v1.1	2025-08-05	Adopted by the Bluetooth SIG Board of Directors.

~~Disclaimer and Copyright Notice~~

~~The copyright inthis specification is owned by the Promoter Members of Bluetooth® Special Interest Group (SIG), Inc. ("Bluetooth SIG"). Use of these specifications and any related intellectual property (collectively, the "Specification"), is governed by the Promoters Membership Agreement among the Promoter Members and Bluetooth SIG (the "Promoters Agreement"), certain membership agreements between Bluetooth SIG and its Adopter and Associate Members (the "Membership Agreements") and the Bluetooth Specification Early Adopters Agreements (1.2 Early Adopters Agreements) among Early Adopter members of the unincorporated Bluetooth SIG and the Promoter Members (the "Early Adopters Agreement"). Certain rights and obligations of the Promoter Members under the Early Adopters Agreements have been assigned to Bluetooth SIG by the Promoter Members.~~

~~Use of the specification by anyone who is not a member of Bluetooth SIG or a party to an Early Adopters Agreement (each such person or party, a "Member"), is prohibited. The legal rights and obligations of each Member are governed by their applicable Membership Agreement, Early Adopters Agreement or Promoters Agreement. No license, express or implied, by estoppel or otherwise, to any intellectual property rights are granted herein.~~

~~Any use of the Specification not in compliance with the terms of the applicable Membership Agreement, Early Adopters Agreement or Promoters Agreement is prohibited and any such prohibited use may result in termination of the applicable Membership Agreement or Early Adopters Agreement and other liability permitted by the applicable agreement or by applicable law to Bluetooth SIG or any of its members for patent, copyright and/or trademark infringement.~~

~~THE SPECIFICATION IS PROVIDED "AS IS" WITH NO WARRANTIES WHATSOEVER, INCLUDING ANY WARRANTY OF MERCHANTABILITY, NONINFRINGEMENT, FITNESS FOR ANY PARTICULAR PURPOSE, SATISFACTORY QUALITY, OR REASONABLE SKILL OR CARE, OR ANY WARRANTY ARISING OUT OF ANY COURSE OF DEALING, USAGE, TRADE PRACTICE, PROPOSAL, SPECIFICATION OR SAMPLE.~~

~~Each Member hereby acknowledges that Products equipped with the Bluetooth technology ("Bluetooth Products") may be subject to various regulatory controls under the laws and regulations of various governments worldwide. Such laws and regulatory controls may govern, among other things, the combination, operation, use, implementation and distribution of Bluetooth products. Examples of such laws and regulatory controls include, but are not limited to, airline regulatory controls, telecommunications regulations, technology transfer controls and health and safety regulations. Each Member is solely responsible for the compliance by their Bluetooth Products with any such laws and regulations and for obtaining any and all required authorizations, permits, or licenses for their Bluetooth products related to such regulations within the applicable jurisdictions. Each Member acknowledges that nothing in the specification provides any information or assistance in connection with securing such compliance, authorizations or licenses. NOTHING IN THE SPECIFICATION CREATES ANY WARRANTIES, EITHER EXPRESS OR IMPLIED, REGARDING SUCH LAWS OR REGULATIONS.~~

~~ALL LIABILITY, INCLUDING LIABILITY FOR INFRINGEMENT OF ANY INTELLECTUAL PROPERTY RIGHTS OR FOR NONCOMPLIANCE WITH LAWS, RELATING TO USE OF THE SPECIFICATION IS EXPRESSLY DISCLAIMED. BY USE OF THE SPECIFICATION, EACH MEMBER EXPRESSLY WAIVES ANY CLAIM AGAINST BLUETOOTH SIG AND ITS PROMOTER MEMBERS RELATED TO USE OF THE SPECIFICATION.~~

~~Bluetooth SIG reserve the right to adopt any changes or alterations to the Specification as it deems necessary or appropriate.~~

~~Copyright © 2011. Bluetooth SIG Inc. All copyrights in the Bluetooth Specifications themselves are owned by Ericsson AB, Lenovo (Singapore) Pte. Ltd., Intel Corporation, Microsoft Corporation, Motorola Mobility, Inc., Nokia Corporation, and Toshiba Corporation. *Other third-party brands and names are the property of their respective owners.~~

Use of this specification is your acknowledgement that you agree to and will comply with the following notices and disclaimers. You are advised to seek appropriate legal, engineering, and other professional advice regarding the use, interpretation, and effect of this specification.

Use of Bluetooth specifications by members of Bluetooth SIG is governed by the membership and other related agreements between Bluetooth SIG and its members, including those agreements posted on Bluetooth SIG's website located at www.bluetooth.com. Any use of this specification by a member that is not in compliance with the applicable membership and other related agreements is prohibited and, among other things, may result in (i) termination of the applicable agreements and (ii) liability for infringement of the intellectual property rights of Bluetooth SIG and its members. This specification may provide options, because, for example, some products do not implement every portion of the specification. All content within the specification, including notes, appendices, figures, tables, message sequence charts, examples, sample data, and each option identified is intended to be within the bounds of the Scope as defined in the Bluetooth Patent/Copyright License Agreement ("PCLA"). Also, the identification of options for implementing a portion of the specification is intended to provide design flexibility without establishing, for purposes of the PCLA, that any of these options is a "technically reasonable non-infringing alternative."

Use of this specification by anyone who is not a member of Bluetooth SIG is prohibited and is an infringement of the intellectual property rights of Bluetooth SIG and its members. The furnishing of this specification does not grant any license to any intellectual property of Bluetooth SIG or its members. THIS SPECIFICATION IS PROVIDED "AS IS" AND

~~Document Terminology~~

~~The Bluetooth SIG has adopted Section 13.1 of the IEEE Standards Style Manual, which dictates use of the words ``shall'', ``should'', ``may'', and ``can'' in the development of documentation, as follows:~~

~~The word *shall* is used to indicate mandatory requirements strictly to be followed in order to conform to the standard and from which no deviation is permitted (*shall* equals *is required to*).~~

~~The use of the word *must* is deprecated and shall not be used when stating mandatory requirements; *must* is used only to describe unavoidable situations.~~

~~The use of the word *will* is deprecated and shall not be used when stating mandatory requirements; *will* is only used in statements of fact.~~

~~The word *should* is used to indicate that among several possibilities one is recommended as particularly suitable, without mentioning or excluding others; or that a certain course of action is preferred but not necessarily required; or that (in the negative form) a certain course of action is deprecated but not prohibited (*should* equals *is recommended that*).~~

~~The word *may* is used to indicate a course of action permissible within the limits of the standard (*may* equals *is permitted*).~~

~~The word *can* is used for statements of possibility and capability, whether material, physical, or causal (*can* equals *is able to*).~~

1 Introduction

The HID over GATT Profile (HOGP) defines the procedures and features to be used by ~~Bluetooth low energy~~ HID Devices ~~using GATT~~ and ~~Bluetooth~~ HID Hosts using ~~GATT.~~

Bluetooth® Low Energy (LE). This profile is an adaptation of the USB HID specification [1] to operate over a Bluetooth ~~low energy~~LE wireless link. For BR/EDR, the Human Interface Device Profile Specification [8] can be used.

The HOGP defines two operation modes: Default Operation mode, which is mandatory, and Hybrid Operation mode, which is optional.

In Default Operation mode, all HID traffic is sent over GATT.

In Hybrid Operation mode, HID traffic that requires higher report rates, flushable transport, or lower latency is sent over LE Isochronous Channels, while HID traffic that does not require higher report rates, flushable transport, or lower latency uses GATT.

~~This profile shall operate over an LE transport only. For BR/EDR, the Bluetooth Human Interface Device Profile Specification shall be used.~~

Commented [Bluetooth1]: 27717

1.1 Profile dependencies

This profile requires the Generic Attribute Profile (GATT), the Battery Service, the Device Information Service, and the Scan Parameters Profile.

~~This specification can be used with Bluetooth Core Specification Version 4.0 or later.~~

1.2 Change History

This section summarizes changes at a moderate level of detail and should not be considered representative of every change made.

1.2.1 Changes from v1.0 to v1.1

1.2.1.1 New and updated features

Feature Name	Description	Location
HID ISO	An option to stream HID Reports over LE Isochronous channels to enable higher report rates, lower latency, and flushing of expired reports.	Many 5: HID ISO requirements 6: HID ISO Service

Table 1.1: New and/or updated features

Commented [Bluetooth2]: 27652

1.2.1.2 Removed features

No features were removed in this version.

1.2.1.3 Errata incorporated into v1.1

Section	Errata
Global	27652
1.2: Conformance	23819
2.5: Multiple service instances	24649
3.1.7: HID Information behavior	14917
4: HID Host requirements and behaviors	24512
4.1: GATT sub-procedure requirements	26703
4.3: Service discovery - Boot Host	26703
4.5: Service discovery - Report Host	26703
5.1: Report interval and latency	27651
5.2: Operation modes	27651
5.3: Configuration of LE Isochronous Channels for HID ISO	27651
6.4: Declaration	27651
6.5.2.1.2: Parameters field	27651
7: Security requirements	14917
7.1: Device security requirements	14917, 15795, 15860
7.2: Host security requirements	14917, 15795, 18330
9: References	22367

Table 1.2: Errata incorporated into v1.1

~~1.2 Conformance~~

~~If conformance to this profile is claimed, all capabilities indicated as mandatory for this profile shall be supported in the specified manner (process-mandatory). This also applies for all optional and conditional capabilities for which support is indicated. All mandatory capabilities, and optional and conditional capabilities for which support is indicated, are subject to verification as part of the *Bluetooth* qualification program.~~

1.3 Language

1.3.1 Language conventions

In the development of a specification, the Bluetooth SIG has established the following conventions for use of the terms "*shall*", "*mandatory*", "*shall not*", "*should*", "*should not*", "*may*", "*optional*", "*must*", and "*can*". In this Bluetooth specification, the terms in Table 1.3 have the specific meanings given in that table, irrespective of other meanings that exist.

Term	Definition
shall *or* mandatory	—used to express what is required by the specification and is to be implemented exactly as written without deviation
shall not	—used to express what is forbidden by the specification
should *or* may *or* optional	— not mandatory. Used to express either: 1. what is recommended by the specification without forbidding anything (“should”) 2. what is permissible within the limits of the specification (“may” or “optional”)
should not	—used to indicate that something is discouraged but not forbidden by the specification
must	—used to indicate either: 1. an indisputable statement of fact that is always true regardless of the circumstances 2. an implication or natural consequence if a separately-stated requirement is followed
can	—used to express a statement of possibility or capability

Table 1.3: Language conventions terms and definitions

Where more than one item is permitted but not required, the choices to include or support those items are independent from one another unless the specification explicitly states otherwise. Each item that is implemented shall be implemented exactly as written without deviation.

Certain terms used in this specification have been updated and are no longer used by Bluetooth SIG. For a list of terms that have been updated and their replacement terms, see the Appropriate Language Mapping Tables [9].

1.3.1.1 Implementation alternatives

When specification content indicates that there are multiple alternatives to satisfy specification requirements, if one alternative is explained or illustrated in an example it is not intended to limit other alternatives that the specification requirements permit.

1.3.1.2 Discrepancies

It is the goal of Bluetooth SIG that specifications are clear, unambiguous, and do not contain discrepancies. However, members can report any perceived discrepancy by filing an erratum and can request a test case waiver as appropriate.

1.3.2 Reserved for Future Use

Where a field in a packet, Protocol Data Unit (PDU), or other data structure is described as "Reserved for Future Use" (irrespective of whether in uppercase or lowercase), the device creating the structure shall

set its value to zero unless otherwise specified. Any device receiving or interpreting the structure shall ignore that field; in particular, it shall not reject the structure because of the value of the field.

Where a field, parameter, or other variable object can take a range of values, and some values are described as "Reserved for Future Use," a device sending the object shall not set the object to those values. A device receiving an object with such a value should reject it, and any data structure containing it, as being erroneous; however, this does not apply in a context where the object is described as being ignored or it is specified to ignore unrecognized values.

When a field value is a bit field, unassigned bits can be marked as Reserved for Future Use and shall be set to 0. Implementations that receive a message that contains a Reserved for Future Use bit that is set to 1 shall process the message as if that bit was set to 0, except where specified otherwise.

The acronym RFU is equivalent to Reserved for Future Use.

1.3.3 Prohibited

When a field value is an enumeration, unassigned values can be marked as “Prohibited.” These values shall never be used by an implementation, and any message received that includes a Prohibited value shall be ignored and shall not be processed and shall not be responded to.

Where a field, parameter, or other variable object can take a range of values, and some values are described as “Prohibited,” devices shall not set the object to any of those Prohibited values. A device receiving an object with such a value should reject it, and any data structure containing it, as being erroneous.

“Prohibited” is never abbreviated.

1.4 Table requirements

Requirements are defined as "Mandatory" (M), "Optional" (O), "Excluded" (X), “Not Applicable” (N/A), or "Conditional" (C.n). Conditional statements (C.n) are listed directly below the table in which they appear.

1.5 Conformance

Commented [Bluetooth3]: 23819

Each capability of this specification shall be supported in the specified manner. This specification may provide options for design flexibility, because, for example, some products do not implement every portion of the specification. For each implementation option that is supported, it shall be supported as specified.

2 Configuration

2.1 Roles

This profile defines three roles: HID Device, Boot Host, and Report Host.

- The HID Device shall be a GATT server.
- The Boot Host shall be a GATT client.
- The Report Host shall be a GATT client.

~~Use of~~ The term HID Host refers to both host roles: Boot Host, and Report Host. A Report Host is required to support a HID Parser and be able to handle arbitrary formats for data transfers (known as Reports~~)~~, whereas a Boot Host is not required to support a HID Parser as all data transfers (Reports) for Boot Protocol Mode are of predefined length and format.

Commented [Bluetooth4]: 27717

2.2 Role~~/~~ and service relationships

Figure 2.1 shows the relationship between services and the profile roles.

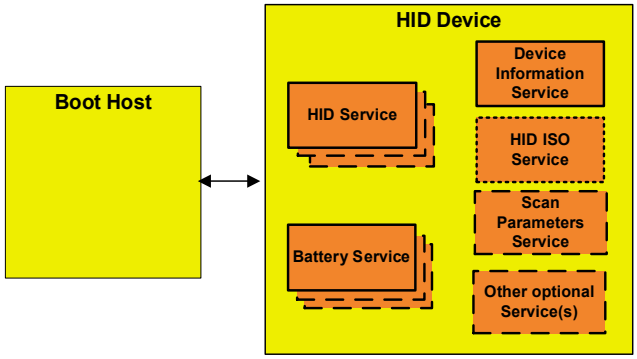

Figure 2.1: Boot Host and HID Device Roles/Service Relationship

Note: Profile roles are represented by yellow boxes and services are represented by orange boxes.

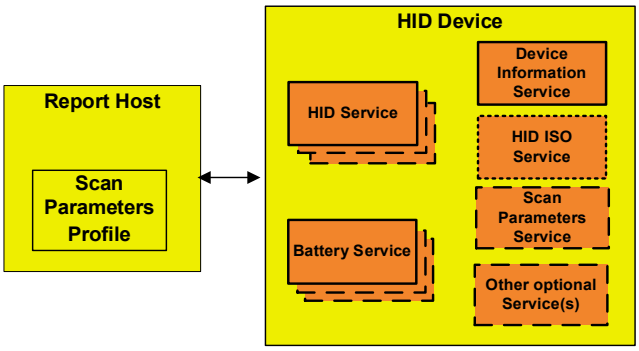

Figure 2.2: Report Host and HID Device Roles/Service Relationships

Note: Profile roles are represented by yellow boxes and services are represented by orange boxes.

The Report Host supports the Scan Client role of the Scan Parameters Profile.

The Boot Host shall not support the Scan Client role of the Scan Parameters Profile.

The HID Device has one or more instances of the HID Service, one or more instances of the Battery Service, a single instance of the Device Information Service, and optionally one instance of the Scan Parameters Service as part of the Scan Server role of the Scan Parameters Profile. A HID Device that supports the HID ISO feature has a single instance of the HID ISO Service. The HID Device may optionally have single or multiple instances of other services.

Commented [Bluetooth5]: 27717

2.3 ~~Concurrent Role~~Concurrency limitations and restrictions

A Boot Host shall not concurrently be a Report Host.

A Report Host shall not concurrently be a Boot Host.

There are no concurrency limitations on either HID Host roles from also being a HID Device.

2.4 Topology limitations and restrictions

The HID Device shall use the GAP Peripheral role.

The Boot Host shall use the GAP Central role.

The Report Host shall use the GAP Central role.

2.5 Multiple service instances

Multiple service instances shall not be supported for the following services:

- Device Information Service.
- Scan Parameters Service
- HID ISO Service

Multiple service instances of the HID Service may be supported to allow implementers to define composite HID Devices whose combined functions require more than 512 octets of data to describe.

- Multiple service instances of the Battery Service may be supported.
- Multiple service instances of ~~the following~~any service other than HID Service, Device Information Service, or Scan Parameters Service may be supported, but are not considered as a part of this profile~~:~~.

Commented [Bluetooth6]: 24649

2.6 Bluetooth specification release compatibility

This specification is compatible with Bluetooth® Core Specification, v6.0 [2] and later.

2.7 Transport dependencies

- This profile shall operate over an LE transport only. ~~Any Service other than HID Service, Device Information Service, or Scan Parameters Service.~~

Implementations that support report intervals less than 2 ms shall use the LE 2M PHY for report intervals less than 2 ms.

3 HID Device requirements

The HID Device shall have one or more instances of the HID Service, one or more instances of the Battery Service, one instance of the Device Information Service, and optionally the Scan Parameters Service, but only a single instance.

The HID Device may support the functionalities defined by the Scan Server role of the Scan Parameters Profile [~~7~~6].

Table 3.1 shows service requirements for the HID Device

Service	Requirement
HID Service	M
Battery Service	M
Device Information Service	M
Scan Parameters Service	O
HID ISO Service	C.1

Table 3.1: HID Device Service Requirements

C.1: Mandatory if the HID ISO feature is supported, otherwise excluded.

3.1 HID Service

This sub-section defines additional HID Device requirements beyond those defined in the HID Service [~~4~~3].

3.1.1 Dependent service requirements

Any non-HID Service ~~which~~that has a characteristic whose value is described within the Report Map characteristic value shall be referenced as an «Include» within the HID Service definition containing that Report Map characteristic.

Commented [Bluetooth7]: 27717

Any characteristic belonging to an external service whose value is described within the Report Map characteristic shall also contain a Report Reference characteristic descriptor within that external service characteristic definition. Only characteristics supporting the mandatory characteristic properties for the intended Report Type shall be described within the Report Map characteristic.

A HID Service shall not include any external service ~~which~~that is already included within another HID Service definition on the GATT Server. These rules prevent separate HID Services from referencing multiple characteristics of the same UUID having identical Report Reference characteristic descriptors.

Commented [Bluetooth8]: 27717

3.1.2 Service Type

All services with the «HID Service» UUID shall be instantiated as a «Primary Service» as part of this profile.

3.1.3 Service UUID~~s~~ AD Type

While in a GAP Discoverable Mode for initial connection to a HID Host, the HID Device should include HID Service UUID(s) defined in [1] in the Service UUID~~s~~ AD type field of the advertising data. ~~Section describes how a HID Host can take advantage of this feature.~~

Commented [Bluetooth9]: 14917

3.1.4 Local Name AD Type

For enhanced user experience, a HID Device should include its Local Name in its Advertising Data or Scan Response Data. ~~Section describes how a HID Host can take advantage of this feature.~~

Commented [Bluetooth10]: 27717

Commented [Bluetooth11]: 14917

3.1.5 Appearance AD Type

For enhanced user experience, a HID Device should include its Appearance in its Advertising Data or Scan Response Data. ~~Section describes how a HID Host can take advantage of this feature.~~

Commented [Bluetooth12]: 27717

Commented [Bluetooth13]: 14917

~~3.1.6 Additional Security Requirements~~

This profile defines additional security requirements in Section ~~6~~7.1 beyond those defined in the HID Service.

3.1.6 Additional service requirements for HID ISO support

When a HID Device supporting the HID ISO feature has more than one instance of the HID Service [3], all Report IDs shall be unique within each Report Type within the HID Device.

3.1.7 HID Information behavior

A HID Device can set the NormallyConnectable flag to TRUE in the HID Information characteristic to expose that it is connections-initiated by the bonded Report Host. When NormallyConnectable is TRUE, a HID Device bonded to at least one Report Host shall be in the GAP Undirected Connectable Mode whenever it is not connected to any HID Host.

Commented [Bluetooth14]: 27917

Refer to Appendix A for details on NormallyConnectable behavior.

Commented [Bluetooth15]: 14917

3.2 Battery Service

This sub-section defines additional HID Device requirements beyond those defined in the Battery Service [~~6~~4].

3.2.1 Service Type

There shall be at least one instance of a service with the «Battery Service» UUID, instantiated as a «Primary Service». If a Battery Level characteristic value is described within the Report Map characteristic value, then the Battery Service definition in which the Battery Level characteristic exists shall be included, using the include definition, within the HID Service definition containing the Report Map characteristic.

3.2.2 Additional security requirements

This profile defines additional security requirements in Section 7.1 beyond those defined in the Battery Service [~~5~~4].

3.3 Device Information Service

This sub-section defines additional HID Device requirements beyond those defined in the Device Information Service [6~~5~~].

3.3.1 Service Type

The Device Information Service shall be instantiated as a «Primary Service» as part of this profile.

3.3.2 Mandatory characteristics

The Device Information Service shall include the PnP ID characteristic for reading the PnP ID fields for the HID Device. This service is defined in the Device Information Service [5].

3.3.3 Additional security requirements

This profile defines additional security requirements in Section 7.1 beyond those defined in the Device Information Service [6~~5~~].

3.4 Scan Parameters Service

This subsection defines additional HID Device requirements beyond those defined in the Scan Parameters Service [7~~6~~].

3.4.1 Additional security requirements

This profile defines additional security requirements in Section 7.1 beyond those defined by the Scan Parameters Service [7~~6~~], if implemented as part of this profile.

3.5 HID ISO support

For a HID Device that supports the HID ISO feature, the requirements in Section 5 are mandatory.

4 HID Host requirements and behaviors

The HID Host defines requirements for observing, connecting to, configuring for notification from, reading from, and writing to a HID Device.

Commented [Bluetooth16]: 27717

This section describes the procedure and characteristic requirements for a HID Host.

Procedure	Section Reference	Boot Host Requirement	Report Host Requirement
Service Discovery	4.3/4.5	M	M
• HID Service Discovery	4.3.1/4.5.1	M	M
• Device Information Service Discovery	4.3.2/4.5.2	O	M
• Battery Service Discovery	4.3.3/4.5.3	O	M
• HID ISO Service Discovery	4.5.4	X	C.4
Characteristic Discovery	4.4/4.6	O	M
• HID Service Characteristic Discovery	4.6.1	O	M
• HID ISO Service Characteristic Discovery	4.6.2	X	C.4
• Device Information Service Characteristic Discovery	4.6.2	O	M
• Battery Service Characteristic Discovery	4.6.3	O	M
Report Map	4.7	X	M
Report	4.8	X	M
Boot Keyboard Input Report	4.12/	C.2/C.3	X
Boot Keyboard Output Report	4.13/	C.2/C.3	X
Boot Mouse Input Report	4.14/	C.2	X
HID Information	4.10	X	M
HID Control Point	4.9	X	C.1
Protocol Mode	4.11/	M	O

Commented [Bluetooth17]: 24512

Procedure	Section Reference	Boot Host Requirement	Report Host Requirement
Non-HID Service characteristic defined within Report Map	4.8.1	X	M
LE HID Operation Mode	4.18	X	C.4
C.1: Mandatory if the Host supports Suspend Mode, otherwise optional. C.2: Mandatory to support at least one of these features. C.3: If one of these features is supported, both features shall be supported. C.4: Mandatory when supporting the HID ISO feature, otherwise excluded.			

Table 4.1: Boot Host and Report Host Requirements

Requirements marked with 'M' are mandatory, 'O' are optional, and 'X' are excluded (not permitted).

4.1 GATT sub-procedure requirements

Requirements in this section represent a minimum set of requirements for a ~~HID Host (GATT Client).~~client. Other GATT sub-procedures may be used if supported by both the GATT Client and GATT Server.

Commented [Bluetooth18]: 27717

Table 4.2 summarizes additional GATT sub-procedure requirements beyond those required by all GATT Clients.

GATT Sub-Procedure	Boot Host Requirement	Report Host Requirement
Discover All Primary Services	C.1	C.1
Discover Primary Service~~s~~ by Service UUID	C.1	C.1
Discover All Characteristics of a Service	O	C.2
Discover Characteristics by UUID	O	C.2
Discover All Characteristic Descriptors	M	M
Find included Services	X	M
Write Without Response	M	M
Write Characteristic Value	M	M
Single Notifications	M	M
Read using Characteristic UUID	M	M
Read Characteristic Value	M	M
Read Long Characteristic Value	X	M

Commented [Bluetooth19]: 26703

GATT Sub-Procedure	Boot Host Requirement	Report Host Requirement
Read Characteristic Descriptors	M	M
Write Characteristic Descriptors	M	M
C.1: Mandatory to support at least one of these sub-procedures. C.2: Mandatory to support at least one of these sub-procedures.		

Table 4.2: Additional GATT Sub-Procedure Requirements

Requirements marked with 'M' are mandatory, 'O' are optional, and 'X' are excluded (not permitted).

4.2 Scan Parameters Profile support

The Report Host shall support the functionality defined in the Scan Parameters Profile [6].

4.2.1 Additional security requirements

This profile defines additional requirements for the Scan Parameters Profile Scan Client role in Section ~~6~~7.2.

4.3 Service discovery - Boot Host

The Boot Host shall perform primary service discovery using either the GATT Discover All Primary Services sub-procedure or the GATT Discover Primary Service~~s~~ by Service UUID sub-procedure. Fast connection parameters and procedures for connection establishment ~~defined in section~~ are recommended to enhance Service Discovery speeds.

Commented [Bluetooth20]: 26703

Commented [Bluetooth21]: 14917

4.3.1 HID Service discovery

The Boot Host shall perform primary service discovery to discover all HID Services.

4.3.2 Device Information Service discovery

The Boot Host may perform primary service discovery to discover the Device Information Service.

4.3.3 Battery Service discovery

The Boot Host may perform primary service discovery to discover the Battery Service.

4.4 Characteristic discovery – Boot Host

4.4.1 HID Service characteristic discovery

The Boot Host may use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure to discover the following characteristics for each HID Service on the GATT Server, if characteristic discovery is supported:

- Protocol Mode characteristic (Section 4.4.1.1)
- Boot Keyboard Input Report characteristic (Section 4.4.1.2)
- Boot Keyboard Output Report characteristic (Section 4.4.1.3)
- Boot Mouse Input Report characteristic (Section 4.4.1.4)

Commented [Bluetooth22]: 27717

If characteristic discovery is not supported, the Boot Host shall use the GATT Read Using Characteristic UUID sub-procedure to read the above HID Service characteristics for Boot Mode operation, replacing normal characteristic discovery.

4.4.1.1 Protocol Mode characteristic

The Boot Host may discover the Protocol Mode characteristic for each HID Service on the GATT Server.

4.4.1.2 Boot Keyboard Input Report characteristic

The Boot Host may discover the Boot Keyboard Input Report characteristic for each HID Service on the GATT Server.

The Boot Host shall discover the associated Client Characteristic Configuration Descriptor of all Boot Keyboard Input Report characteristics using the GATT Discover All Characteristic Descriptors sub-procedure.

4.4.1.3 Boot Keyboard Output Report characteristic

The Boot Host may discover the Boot Keyboard Output Report characteristic for each HID Service on the GATT Server.

4.4.1.4 Boot Mouse Input Report characteristic

The Boot Host may discover the Boot Mouse Input Report characteristic for each HID Service on the GATT Server.

The Boot Host shall discover the associated Client Characteristic Configuration Descriptor of all Boot Mouse Input Report characteristics using the GATT Discover All Characteristic Descriptors sub-procedure.

4.4.2 Device Information Service characteristic discovery

The Boot Host may use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure to discover the following characteristic of the Device Information Service, if characteristic discovery is supported:

- PnP ID characteristic (Section 4.4.2.1)

If characteristic discovery is not supported, then the Boot Host may use the GATT Read Using Characteristic UUID sub-procedure to read the above Device Information Service characteristic, replacing normal characteristic discovery.

Commented [Bluetooth23]: 27717

Commented [Bluetooth24]: 27717

4.4.2.1 PnP ID characteristic

The Boot Host may discover the PnP ID characteristic.

4.4.3 Battery Service characteristic discovery

The Boot Host may use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure to discover the following characteristic of the Battery Service, if characteristic discovery is supported:

- Battery Level characteristic (Section 4.4.3)

If characteristic discovery is not supported, then the Boot Host may use the GATT Read Using Characteristic UUID sub-procedure to read the above Battery Service characteristic, replacing normal characteristic discovery.

Commented [Bluetooth25]: 27717

4.4.3.1 Battery Level characteristic

The Boot Host may discover the Battery Level characteristic.

4.5 Service discovery – Report Host

The Report Host shall perform primary service discovery using either the GATT Discover All Primary Services sub-procedure or the GATT Discover Primary Services by Service UUID sub-procedure. Fast connection parameters and procedures for connection establishment ~~defined in section~~ are recommended to enhance Service Discovery speeds.

Commented [Bluetooth26]: 26703

Commented [Bluetooth27]: 14917

If the Report Host supports an ATT_MTU larger than the default ATT_MTU, then the Report Host shall use the GATT Exchange MTU sub-procedure prior to performing service discovery.

Commented [Bluetooth28]: 27717

4.5.1 HID Service discovery

The Report Host shall perform primary service discovery to discover all HID Services.

4.5.2 Device Information Service discovery

The Report Host shall perform primary service discovery to discover the Device Information Service.

4.5.3 Battery Service discovery

The Report Host may perform primary service discovery to discover all Battery Services.

The Report Host shall perform relationship discovery to find included services to discover all Battery Services with characteristics described within a HID Service Report Map characteristic value.

Note: Multiple instances of the Battery Service can be distinguished using the Characteristic Presentation Format characteristic descriptor of the Battery Level characteristic as defined by the Battery Service [4]. Within this profile, multiple Battery Level characteristics referenced within the Report Map characteristic are distinguished by the Report Reference characteristic descriptor.

4.5.4 HID ISO Service discovery

If the Report Host supports the HID ISO feature, then the Report Host shall perform primary service discovery to discover the HID ISO Service.

4.6 Characteristic discovery – Report Host

As required by GATT, the Report Host must be tolerant of additional optional characteristics of services used with this profile and used outside of this profile.

4.6.1 HID Service characteristic discovery

The Report Host shall use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure to discover the characteristics of all HID services.

The Report Host shall use the GATT Discover All Characteristic Descriptors sub-procedure to discover the characteristic descriptors described in the following sections.

4.6.1.1 Report Map characteristic

The Report Host shall discover all Report Map characteristics.

The Report Host shall discover all External Report Reference characteristic descriptors for each Report Map characteristic.

4.6.1.2 Report characteristics

The Report Host shall discover all Report characteristics.

The Report Host shall discover the associated Client Characteristic Configuration Descriptor of all Report characteristics.

The Report Host shall discover the associated Report Reference characteristic descriptor of all Report characteristics.

4.6.1.3 HID Control Point characteristic

The Report Host shall discover all HID Control Point characteristics, if the Report Host supports Suspend mode, to allow the Report Host to send control commands to HID Devices whenever the Report Host enters a low power Suspend Mode.

4.6.1.4 HID Information characteristic

The Report Host shall discover all HID Information characteristics.

4.6.1.5 Protocol Mode characteristic

The Report Host may discover the Protocol Mode characteristic for each HID Service on the GATT server.

4.6.2 Device Information Service characteristic discovery

The Report Host shall discover characteristics of the Device Information Service.

In order for the Report Host to discover the characteristics of the Device Information Service, it shall use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure.

4.6.2.1 PnP ID characteristic

The Report Host shall discover the PnP ID characteristic.

4.6.3 Battery Service characteristic discovery

The Report Host shall discover the characteristics of all Battery Services.

In order for the Report Host to discover the characteristics of all Battery Services, it shall use either the GATT Discover All Characteristics of a Service sub-procedure or the GATT Discover Characteristics by UUID sub-procedure.

4.6.3.1 Battery Level characteristic

The Report Host shall discover all Battery Level characteristics to find Battery Level characteristics referenced within the External Report Reference characteristic descriptor and their associated Report Reference characteristic descriptors.

4.6.4 HID ISO Service characteristic discovery

4.6.4.1 HID ISO Properties characteristic

The Report Host shall discover the HID ISO Properties characteristic when supporting the HID ISO feature.

4.6.4.2 LE HID Operation Mode characteristic

The Report Host shall discover the LE HID Operation Mode characteristic when supporting the HID ISO feature.

4.7 Report Map behavior

The Report Map characteristic shall return the HID Report Descriptor when read.

The HID Report Descriptor is defined in the USB HID specification [~~2~~1].

The Report Host shall read all characteristic descriptors of the Report Map characteristic to allow the Report Host to map information within the Report Map characteristic to external service characteristics used to transfer data described by the information between the Report Host and HID Device.

4.8 Report behavior

The Report characteristic is used to transfer HID Service data between the Report Host and the HID Device.

The Report Host shall enable notifications, via the Client Characteristic Configuration descriptor, of the Report characteristic for all instances of the Report characteristic where the Report Type as defined in the Report Reference characteristic descriptor refers to an Input Report.

The Boot Host shall ignore notifications of the Report characteristic.

4.8.1 Translation layer

Note: This profile delivers USB-IF HID data over ~~the~~ Bluetooth ~~air interface~~ by means of the Generic Attribute Profile [1]. If an implementation of the Report Host were to utilize a translation layer located between the GATT layer on the Report Host and the USB HID class driver, it would need to conform to the behavior described in this section.

According to Sections 4.5 and 4.6, the Report Host shall perform service discovery, characteristic discovery, and characteristic descriptor discovery in the specified manner.

Commented [Bluetooth29]: 27717

A Report ID and a Report Type defined within the Report Map characteristic and referenced within Report Reference characteristic descriptors allows the Report Host to route GATT characteristic value data into and out of the USB HID class driver, and allows the Report Host to route USB HID class driver data into and out of GATT characteristic values.

Commented [Bluetooth30]: 27717

Commented [Bluetooth31]: 27717

For each separate Report ID and Report Type combination defined within the Report Map characteristic value, there shall be one of the following:

1. A HID Service Report characteristic and Report Reference characteristic descriptor within the Report characteristic definition.
2. An external service characteristic whose UUID is supplied via an External Report Reference characteristic descriptor within the Report Map characteristic definition, and whose characteristic value contains a Report Reference characteristic descriptor within the external service characteristic definition. All External Report Reference characteristic descriptors shall contain unique values within a HID Service definition.

For data transferred from the HID Device to the Report Host, the Report ID is prepended to data received by the Report Host (usually either a notification of a Report characteristic value, or as a read response of a Report characteristic value, for HID Service data) before being passed to a USB HID Class driver.

For data transferred to the HID Device from the Report Host, the Report ID is removed from data received from a USB HID Class driver before being transmitted to the HID Device (usually a write command to a Report characteristic value or as a write request to a Report characteristic value for HID Service data).

Commented [Bluetooth32]: 27717

4.9 HID Control Point behavior

The HID Control Point characteristic is a control-point characteristic as defined in Volume 3, Part F, Section 3.2.6, Part F, Volume 3 of [2]. The HID Control Point characteristic allows the Report Host to signal the HID Device that the Report host is entering or exiting a power saving mode known as Suspend Mode (see [98], §7.4.2).

Commented [Bluetooth33]: 27717

4.10 HID Information behavior

The HID Information characteristic value contains the bcdHID and bcountryCode fields as defined by the USB HID specification [21].

When a system enters a low-power Suspend Mode, the RemoteWake flag shall be used to determine whether the Report Host includes the HID Device in the set of devices that can wake it up.

If the RemoteWake flag is FALSE, then the HID device does not consider itself remote wakeup-capable, and the Report Host can exclude the HID Device from the set of devices that can wake the Report Host up.

When a Report Host is exiting a low power Suspend Mode, the NormallyConnectable flag shall be used to determine whether the Report Host can connect to the HID Device before any user interaction occurs on the HID device. This may be used to improve the perceived responsiveness of the system.

4.11 Protocol Mode behavior

The Protocol Mode characteristic allows reading and writing of the protocol mode of the HID Service, and to set the desired protocol mode.

The Boot Host shall write to the Protocol Mode characteristic for each HID Service on the GATT Server, and set the characteristic value to the defined value for Boot Protocol Mode following connection establishment. There are no requirements on a Report Host to use the Protocol Mode characteristic.

4.12 Boot Keyboard Input Report behavior

The Boot Keyboard Input Report characteristic is used to transfer HID Service data representing keyboard keystrokes between a HID Service corresponding to a HID Device operating in Boot Protocol Mode as a keyboard and a Boot Host.

If the Boot Host supports the Boot Keyboard Input Report characteristic, then it shall enable notifications of the Boot Keyboard Input Report characteristic using the Client Characteristic Configuration descriptor.

The Report Host shall ignore notifications of the Boot Keyboard Input Report characteristic.

4.13 Boot Keyboard Output Report behavior

The Boot Keyboard Output Report characteristic is used to transfer HID Service data representing the status of LED's visible to the user between a HID Service corresponding to a HID Device operating in Boot Protocol Mode as a keyboard and a Boot Host.

4.14 Boot Mouse Input Report behavior

The Boot Mouse Input Report characteristic is used to transfer HID Service data representing pointer coordinates between a HID Service corresponding to a HID Device operating in Boot Protocol Mode as a mouse and a Boot Host.

If the Boot Host supports the Boot Mouse Input Report characteristic, then it shall enable notifications of the Boot Mouse Input Report characteristic using the Client Characteristic Configuration descriptor.

The Report Host shall ignore notifications of the Boot Mouse Input Report characteristic.

4.15 Battery Level behavior

The Battery Level characteristic may either be read by the HID Host, or be enabled for notification using the Client Characteristic Configuration Descriptor, by the HID Host. The HID Host should minimize the frequency of reads of the Battery Level characteristic value to avoid significant impact on the battery life of the HID Device. The HID Host may use the information returned in a read response or a notification of the Battery Level characteristic value to display the battery level of the HID Device.

4.16 PnP ID behavior

The PnP ID characteristic value shall be read by the Report Host upon initial connection establishment and may be cached afterwards. The PnP ID characteristic value may be read by the Boot Host upon initial connection establishment and may be cached afterwards.

Commented [Bluetooth34]: 27717

Commented [Bluetooth35]: 27717

Commented [Bluetooth36]: 27717

Commented [Bluetooth37]: 27717

Commented [Bluetooth38]: 27717

The HID Host can use the information returned in the PnP ID characteristic value to find representative icons or load associated support software.

Note: The Appearance AD type ~~(see section)~~ exists and may be common to multiple distinct devices, however icons unique to a single manufacturer, based on the PnP ID characteristic value, can be displayed on a per-device basis.

Commented [Bluetooth39]: 14917

4.17 Information sharing between HID Hosts

The Boot Host and Report Host shall share bonding information and information regarding «Service changed» indications. If a bond is deleted from a Report Host, then the bonding information shall be removed from the Boot Host. If a bond is deleted from a Boot Host, then the bonding information shall be removed from the Report Host.

Commented [Bluetooth40]: 27717

If a «Service changed» indication is received by the Report ~~Mode~~ Host when connected to the HID Device, then the Report Host shall make the Boot Host aware of the «Service changed» indication and any information contained therein. If a «Service changed» indication is received by the Boot ~~mode~~ Host when connected to the HID Device, then the Boot ~~mode~~ Host shall make the Report ~~mode~~ Host aware of the «Service changed» indication and any information contained therein.

Commented [Bluetooth41]: 27717

4.18 LE HID Operation Mode behavior

The LE HID Operation Mode characteristic is used to switch the operation mode between Default Operation mode and Hybrid Operation mode at the application layer. For a Report Host that supports the HID ISO feature, the client requirements in Section 5.2 are mandatory.

4.19 HID ISO support

For a Report Host that supports the HID ISO feature, the requirements in Section 5.3, Section 5.4, Section 5.5, and Section 5.6 are mandatory.

5 Connection Establishment

This section describes the connection establishment and connection termination procedures used by a HID Host and HID Device in certain scenarios.

5.1 HID Device Requirements

5.1.1 Device Discovery

The HID Device should use the GAP *Limited Discoverable Mode* when establishing an initial connection. The T_{GAP}(lim_adv_timeout) used during GAP *Limited Discoverable Mode* may be larger than the value specified in [3], Section 16, Appendix A in the GAP specification but the value shall be less than or equal to 180 seconds.

5.1.2 Connection Procedure for Non-bonded Devices

This procedure is used for connection establishment when the HID Device connects to a HID Host to which it is not bonded. This may be initiated through user interaction.

It is recommended that the HID Device advertises using the parameters in Table 5.1. The interval values in the first row are designed to attempt fast connection during 180 seconds.

Advertising Duration	Parameter	Value
180 seconds (fast connection)	Advertising Interval	30 ms to 50 ms

***Table 5.1**: Recommended Advertising Parameters for Non-bonded Devices*

The advertising interval and time to perform advertising should be configured with consideration for user expectations of connection establishment time.

The HID Device shall accept any valid values for connection interval and connection latency set by the HID Host, as a fast connection interval may be requested in order for the HID Host to quickly perform service discovery and enable encryption.

After service discovery and encryption, the HID Device should request to change to the preferred connection parameters that best suit its use case.

To request a change in the connection parameters, the HID Device shall use the L2CAP Connection Parameter Update Request as described in [Vol.3] Part A, Section 4.20 of [3].

If the HID Host receives the L2CAP Connection Parameter Update request but has not yet completed service discovery or has not completed encryption, the HID Host may send the L2CAP Connection Parameter Update Response with the *Result* field indicating that the request has been rejected. In this case, the HID Device may wait and re-send a new L2CAP Connection Parameter Update Request no sooner than T_{GAP}(conn_param_timeout) (see [3] Volume 3, Part C, Section 9.3.9.2) seconds later.

If a connection is not established within a time limit defined by the HID Device, the HID Device may exit the GAP connectable mode.

The HID Device shall be in a bondable mode during this procedure to optimize connecting to the HID Host, again using the procedure described in Section 5.1.3 and section 5.1.4.

If a bond is created, the HID Device should write the address of the HID Host in the HID Device controller's white list and set the HID Device controller's advertising filter policy to 'process scan and connection requests only from devices in the White List'.

Once connected, the HID Device should wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to complete configuration.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications but the HID Device has no data to transfer, the HID Device should wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications and the HID Device has data to transfer, after it has completed its transfer, it should perform the GAP *Terminate Connection* procedure after waiting for an idle connection timeout.

5.1.3 Device-Initiated Connection Procedure for Bonded Devices

This procedure is used after the HID Device has bonded with the Host using the connection procedure in section 5.1.2. The HID Device may initiate the connection procedure when commanded by the user or autonomously when a notification is pending.

A HID Device shall enter the GAP Undirected Connectable Mode or Directed Connectable Mode either when commanded by the user to initiate a connection to a HID Host or when the HID Device has one or more notifications to send to a previously connected HID Host.

The HID Device when bonded should use whichever advertising filter policy it has previously configured when using the connection procedure in section 5.1.2.

The HID Device should use the recommended advertising interval values shown in Table 5.2. The interval values in the first row are designed to attempt fast connection during the first 1.28 seconds; however, if a connection is not established within that time, the interval values in the second row are designed to reduce power consumption for devices that continue to advertise.

Advertising Duration	Parameter	Value
1.28 seconds (low latency) – Option 1	Advertising mode	Directed
30 seconds (higher latency) - Option 2	Advertising mode	Undirected
	Advertising Interval	20 ms to 30 ms

***Table 5.2**: Recommended advertising parameters for device-initiated connection of bonded devices*

The advertising interval and time to perform advertising should be configured with consideration for user expectations of connection establishment time.

The HID Device shall accept any valid values for connection interval and connection latency set by the HID Host until service discovery, bonding and/or encryption is complete. Only after that should the HID Device request to change to its preferred connection parameters which best suit its use case.

If a connection is not established within a time limit defined by the HID Device, the HID Device may exit the GAP connectable mode or switch to the Advertising parameters shown in Table 5.2 if NormallyConnectable is TRUE.

When a connection is established with a notification pending, the HID Device shall send one or more notifications to the HID Host.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications but the HID Device has no data to transfer, it should wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications and the HID Device has data to transfer, after it has completed its transfer, it should perform the GAP *Terminate Connection* procedure after waiting for an idle connection timeout.

Refer to Appendix A for details on NormallyConnectable behavior.

5.1.4 Host-Initiated Connection Procedure for Bonded Devices

This procedure is used after the HID Device has bonded with the HID Host using the connection procedure in section 5.1.2. The HID Host may initiate the connection procedure when commanded by the user or autonomously when data such as LED status needs to be transmitted to the HID Device.

A HID Device that wishes to be able to accept connections initiated by bonded Report Hosts shall set the NormallyConnectable flag to TRUE in the *HID Information* characteristic. When NormallyConnectable is TRUE, a HID Device bonded to at least one Report Host shall be in the GAP Undirected Connectable Mode whenever it is not connected to any HID Host.

The HID Device when bonded should use whichever advertising filter policy it has previously configured when using the connection procedure in section 5.1.2.

The HID Device should use the recommended advertising interval values shown in Table 5.3.

Advertising Duration	Parameter	Value
Permanent (reduced power)	Advertising mode	Undirected
	Advertising Interval	1 s to 2.5 s

***Table 5.3**: Recommended Advertising Parameters for Host-Initiated Connection of Bonded Devices*

The advertising interval and time to perform advertising should be configured with consideration for user expectations of connection establishment time.

The HID Device shall accept any valid values for connection interval and connection latency set by the HID Host until service discovery, bonding and encryption is complete. Only after that should the HID Device request to change to its preferred connection parameters which best suit its use case.

When a connection is established with a notification pending, the HID Device shall send one or more notifications to the HID Host.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications but the HID Device has no data to transfer, it should wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications and the HID Device has data to transfer, after it has completed its transfer, it should perform the GAP *Terminate Connection* procedure after waiting for an idle connection timeout.

Refer to Appendix A for details on NormallyConnectable behavior.

5.1.5 Link Loss Reconnection Procedure

When a connection is terminated due to link loss a HID Device should attempt to reconnect to the HID Host by entering a GAP connectable mode using the recommended advertising interval values shown in Table 5.2. The HID Device may also wait until it has data to transmit or until the next user activity is detected.

5.1.6 Idle Connection

The HID Device may perform the GAP *Terminate Connection* procedure if the connection is idle for a time period, which is implementation specific. If the HID Device supports the Scan Parameters Service, the Report Host shall follow the procedures defined in the *Scan Parameters Profile* to write its intended scanning behavior to the *Scan Interval Window* characteristic, and should not terminate the connection, but should wait for the HID Device to terminate the connection.

The HID Device may use the scan parameters written to the *Scan Interval Window* characteristic by the Report Host when deciding whether to remain connected to the Report Host or to terminate the connection, depending on the power consumption or reconnection latency requirements of the HID Device.

5.2 Host Requirements

5.2.1 Device Discovery

The HID Host should use the GAP *Limited Discovery Procedure* to discover HID Devices.

The HID Host may identify devices based on their Service UUIDs AD Type data and display devices supporting HID Services to the user before initiating a connection. The HID Host may also identify devices based on their Local Name AD Type data to provide a meaningful name for the device. The HID Host may also identify devices based on their Appearance AD Type data to display meaningful icons for the device.

5.2.2 Connection Procedure for Non-bonded Devices

This procedure is used for connection establishment when the HID Host connects to a HID Device to which it is not bonded. This may be initiated through user intervention.

A HID Host may use one of the following GAP connection procedures defined in [3], Volume 3, Part C, §9.3, based on its connectivity requirements:

1. *General Connection Establishment Procedure*. The HID Host may use this procedure when it requires connection to one or more HID Devices. This procedure allows a HID Host to connect to a HID Device discovered during a scan without using the white list.
    - *Direct Connection Establishment Procedure*. The HID Host may use this procedure when it requires connection to a single HID Device.

- *Auto Connection Establishment Procedure*. The HID Host may use this procedure when it requires connecting to one or more HID Devices. This procedure will automatically connect to a HID Device in the white list.
- *Selective Connection Establishment Procedure*. The HID Host may use this procedure when it requires connecting to one or more HID Devices. This procedure allows a HID Host to connect to a HID Device discovered during a scan while using the white list.

The HID Host should use the recommended Scan Interval and Scan Window values shown in Table 5.4.

For 180 seconds (or optionally continuously for mains powered devices), the HID Host should use the recommended Scan Window / Scan Interval pair to attempt fast connection.

Scan Duration	**Parameter**	**Value**
180 seconds (fast connection)	Scan Interval	22.5ms
	Scan Window	11.25ms

***Table 5.4**: Recommended Scan Parameters for Non-bonded Devices*

The HID Host shall bond with the HID Device during this procedure to optimize reconnecting to the HID Device using the procedure in section 5.2.3 and section 5.2.4.

If a bond is created, the HID Host should write the address of the HID Device in the HID Host controller's white list and set the HID Host controller's initiator filter policy to 'process connectable advertisement packets'.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications, the HID Host should wait for an idle connection timeout (refer to section 5.1.6) before terminating the connection in case the HID Device has any notifications pending.

The HID Device typically terminates the connection after completion of data transfer, but may wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

5.2.3 Device-Initiated Connection Procedure for Bonded Devices

This procedure is used after the HID Host has bonded with the HID Device using the connection procedure in section 5.2.2.

The HID Device may initiate the connection procedure either when commanded by the user or autonomously when a notification is pending.

A HID Host may use one of the GAP connection procedures (see section 5.2.2) based on its connectivity requirements.

The HID Host should use the scan interval and scan window values shown in Table 5.5. Scan intervals greater than 1.28 s and scan windows shorter than 11.25 ms should not be used.

Scan Duration	Parameter	Value
Permanent (reduced power)	Scan Interval	1.28s
	Scan Window	11.25ms

***Table 5.5**: Recommended Scan Parameters for Device-Initiated Connection of Bonded Devices*

The HID Host should use a scan window and scan interval suitable to its power and connection time requirements. Increasing the scan window increases the power consumption, but decreases the connection time.

The scan interval and scan window should be configured with consideration for user expectations of connection establishment time.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications, the HID Host should wait for an idle connection timeout (see section 5.1.6) before terminating the connection in case the HID Device has any notifications pending.

The HID Device typically terminates the connection after completion of data transfer, but may wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

The HID Host shall start encryption after connection establishment to verify the status of the bond.

If encryption fails upon connection establishment (i.e., the bond no longer exists), the HID Host must, after user interaction, perform bonding, perform service discovery (unless the HID Host had previously determined that the HID Device did not have the «Service Changed» characteristic), and reconfigure the HID Device *Client Characteristic Configuration* descriptor before using any of the this profile's services in case the previous configuration was altered or lost.

5.2.4 Host-Initiated Connection Procedure for Bonded Devices

This procedure is used after the HID Host has bonded with the HID Device using the connection procedure in section 5.2.2.

The HID Host may initiate the connection procedure when commanded by the user or autonomously when data such as LED status needs to be transmitted to the HID Device.

- Note: The Report Host should only attempt to connect to a bonded HID Device if the HID Device has the NormallyConnectable flag set to TRUE.

A HID Host may use one of the connection procedures (see section 5.2.2) based on its connectivity requirements.

The HID Host should use the recommended scan interval and scan window values shown in Table 5.6.

Scan Duration	Parameter	Value
30 seconds (fast connection)	Scan Interval	30ms to 60ms*
	Scan Window	30ms

***Table 5.6**: Recommended Scan Parameters for Host-Initiated Connection of Bonded Devices*

* A scan interval of 60ms is recommended when the HID Host is supporting other operations to provide a 50% scan duty cycle versus 100% scan duty cycle.

If a connection is not established within that time, the HID Host may exit the GAP connection procedure.

The HID Host should use a scan window and scan interval suitable to its power and connection time requirements. Increasing the scan window increases the power consumption, but decreases the connection time.

The scan interval and scan window should be configured with consideration for user expectations of connection establishment time.

If the *Client Characteristic Configuration* descriptor has been configured to enable notifications, the Host should wait for an idle connection timeout (refer to section 5.1.6) before terminating the connection in case the HID Device has any notifications pending.

The HID Device typically terminates the connection after completion of data transfer, but may wait for an idle connection timeout (refer to section 5.1.6) to allow the HID Host to terminate the connection once its actions are complete.

The HID Host shall start encryption after connection establishment to verify the status of the bond.

If encryption fails upon connection establishment (i.e. the bond no longer exists), the HID Host must, after user interaction, perform bonding, perform service discovery (unless the Host had previously determined that the HID Device did not have the «Service Changed» characteristic), and configure the HID Device *Client Characteristic Configuration* descriptor again before using any of the services referenced by this profile in case the configuration was altered or lost.

Refer to Appendix A for details on NormallyConnectable behavior.

5.2.5 Link Loss Reconnection Procedure

When a connection is terminated due to link loss, the HID Host should attempt to reconnect to the HID Device using any of the GAP connection procedures (see section 5.2.2). The Report Host should use the parameters in Table 5.6 if the HID Device has set the NormallyConnectable flag to TRUE.

5.2.6 Fast Connection Interval

To avoid very long service discovery and encryption times, the HID Host should use the connection intervals defined in Table 5.7 in the connection request.

Parameter	Value
Minimum Connection Interval	7.5 ms
Maximum Connection Interval	50 ms

***Table 5.7**: Recommended Fast Connection Parameters*

If, at any time, lower latency is required, for example to perform encryption key refresh or encryption setup, this should be preceded with a connection parameter update to the minimum and maximum connection interval values defined in Table 5.7 and a slave latency value of zero. This fast connection interval should be maintained as long as lower latency is required. Afterwards, the connection parameters

~~should return to those specified by the HID Device using the L2CAP Connection Parameter Update procedure.~~

5 HID ISO requirements

When supporting the HID ISO feature, Input reports and/or Output reports can be configured to be sent over LE Isochronous Channels using a Connected Isochronous Stream (CIS).

One or more reports can be made available for sending over LE Isochronous Channels in Hybrid Operation mode by the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic. One Input Report and/or one Output Report from the available reports can be selected for transmission over LE Isochronous Channels in Hybrid Mode.

5.1 Report interval and latency

The term “report interval” refers to the nominal time difference between the opportunities to transmit reports created at either the HID Device (Input report) or HID Host (Output report).

For HID Reports sent over LE Isochronous channels in Hybrid Operation mode, the SDU interval is the same value as the report interval.

Commented [SIG42]: 27651

End-to-end latency for an input report is the time from when a human action is performed on the HID Device until the action is detected by an application on the HID Host.

End-to-end latency for an output report is the time from when an application on the HID Host sends a message to an actuator in the HID Device until the effect of the message reaches the user.

Both report interval and end-to-end latency can be important for the user experience.

The report interval is set by the HID Host selecting an SDU interval supported by both the HID Device and HID Host. The HID Host should choose the minimum report interval that is supported by both devices.

The selected SDU interval will limit the minimum end-to-end latency.

The end-to-end delay is also influenced by several other factors, such as sample acquisition, sample processing, buffering in the transmitting device, maximum spacing between transmit opportunities, buffering in the receiving device, and signaling between layers.

Link Layer parameters for the CIS will impact the average latency as well as the latency variance.

For optimal latency performance, when the report rate is less than 5 ms, the implementer will need to consider the detailed Link Layer timing for the CIS and ACL PDUs (see Appendix C.2 for an example). Section 5.3 describes the Link Layer behavior for optimal latency performance.

5.2 Operation modes

The LE HID Operation Mode characteristic is used to switch the operation mode between Default Operation mode and Hybrid Operation mode at the application layer.

When a connection between a HID Device and a HID Host is established, the initial operation mode shall be Default Operation mode, which uses only GATT for sending and receiving reports. In Hybrid Operation mode, the HID Report(s) identified by a command from the HID Host are sent over LE Isochronous Channels while other reports are sent over GATT. The procedures in Section 5.2.1 and Section 5.2.2 are designed to keep the HID Device and the HID Host in the same operation mode at any given time.

Commented [SIG43]: 27651

Figure 5.1 shows the simplified state diagram of the HID Device and HID Host operation modes.

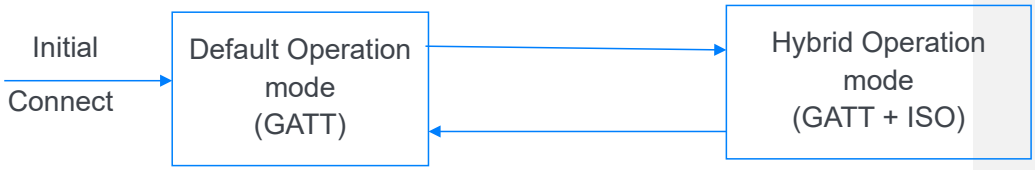

Figure 5.1: Simplified operation mode state diagram

Section 5.2.1 and Section 5.2.2 describe how the HID Host can change the operation mode and how the HID Device may request an operation mode change. The sequence for changing the operation mode is explained in Appendix B.

5.2.1 Host-initiated operation mode change

To change the operation mode to Hybrid Operation mode and to enable certain HID Reports to be sent over LE Isochronous Channels, the HID Host shall write the LE HID Operation Mode characteristic with the Opcode field set to Select Hybrid Operation Mode and the Parameters field set to indicate the report interval to be used, the SDU sizes to be used, and the list of HID Reports (identified by Report Type and Report ID) that shall be sent over LE Isochronous Channels when in Hybrid Operation mode. At most one Input Report and/or one Output Report shall be sent over LE Isochronous Channels in a given Hybrid mode session.

After sending the Select Hybrid Operation Mode Opcode and receiving a successful response, the HID Host shall configure the CIS to be used for HID ISO traffic and initiate the Connected Isochronous Stream Creation procedure. The HID Host shall continue in Default Operation mode (still using GATT) until the LE Connected Isochronous stream is successfully established and then enter Hybrid Operation mode.

After receiving the Select Hybrid Operation Mode Opcode, the HID Device shall continue in Default Operation mode (still using GATT) until the LE Connected Isochronous stream is established and then enter Hybrid Operation mode.

To change the operation mode to Default Operation mode, the HID Host shall write the LE HID Operation Mode characteristic with the Opcode field set to Select Default Operation Mode and the Parameters field empty, change the state to Default Operation mode, and initiate termination of the CIS, in that order.

After receiving the Select Default Operation Mode Opcode, the HID Device shall change the state to Default Operation mode without waiting for termination of the CIS.

If the HID Device detects an error in the command written to the LE HID Operation Mode characteristic, then the HID Device shall respond with one of the error codes defined in Section 6.2.

5.2.2 Device request to change operation mode

If the HID Device has the Device Mode Change Supported bit in the HID ISO Properties characteristic set, then the HID Device may request an operation mode change by indicating the LE HID Operation Mode characteristic with the corresponding Opcode. If the HID Device is requesting to change the operation mode to Hybrid Operation mode, then the Parameters field is set to indicate the desired report interval and the list of HID Reports (identified by Report Type and Report ID) that the HID Device prefers to send over LE Isochronous Channels when in Hybrid Operation mode. After receiving the request, the HID Host should perform the Host-initiated operation mode change as described in Section 5.2.1.

5.3 Configuration of LE Isochronous Channels for HID ISO

The HID Host shall read the HID ISO Properties characteristic on each connection to discover the properties of the HID Device. The HID Host shall configure either an existing or a new Connected Isochronous Group (CIG). The HID Host shall create and configure a single CIS in the CIG to transfer ISO reports in Hybrid Operation mode. The CISes created for HID Devices that are also implementing the HID ISO feature and the CISes for other profiles can be created in the same CIG or in different CIGs. Note that combining CISes in a CIG constrains the link parameters of each CIS ([2] Volume 6, Part B, Section 4.5.14), and will limit which CISes that can be combined into one CIG.

Commented [SIG44]: 27651

The CIS for HID ISO data shall be configured with the SDU interval (parameters SDU_Interval_P_to_C and SDU_Interval_C_to_P when using HCI) set equal to one of the report intervals supported by the HID Device, as indicated by the Supported Report Intervals field of the HID ISO Properties characteristic.

The maximum SDU size for the Central to Peripheral direction (parameter Max_SDU_C_to_P when using HCI) shall be set to a value greater than or equal to the length of the longest Output Report enabled over ISO plus the overhead of the HID ISO protocol (3 octets). When the HID Host device is not constrained by other use cases, the maximum SDU size for the Central to Peripheral direction should be set to the value of the Max SDU Size for Output Reports field of the HID ISO Properties characteristic. When the maximum SDU size for the Central to Peripheral direction is set to a value less than the value of the Preferred SDU Size for Output Reports field of the HID ISO Properties characteristic, then the HID Device may have to reduce the robustness or reduce the effective report rate.

The maximum SDU size for the Peripheral to Central direction (parameter Max_SDU_P_to_C when using HCI) shall be set to a value greater than or equal to the length of the longest Input Report enabled over ISO plus the overhead of the HID ISO protocol (3 octets). When the HID Host device is not constrained by other use cases, the maximum SDU size for the Peripheral to Central direction should be set to the value of the Max SDU Size for Input Reports field of the HID ISO Properties characteristic. When the maximum SDU size for the Peripheral to Central direction is set to a value less than the value of the Preferred SDU Size for Input Reports field of the HID ISO Properties characteristic, then the HID Device may have to reduce the robustness or reduce the effective report rate.

To minimize latency contribution from the Link Layer protocols, the Controller in the HID Host should be configured to use an ISO subinterval less than or equal to the SDU interval when the SDU interval is less than the ISO interval and to send unframed SDUs.

Note that the HID Host must select a combination of SDU interval and SDU size that allows the Controller to schedule the Central to Peripheral PDU (MPT_C), the Peripheral to Central PDU (MPT_P), and the frame spacing (T_IFS and T_MSS) within one ISO subinterval. See Appendix C.2 for details on Link Layer timing.

To minimize latency contribution from the Bluetooth implementation, the Controller in both the HID Host and the HID Device should send an SDU received from its Host at the first available transmit opportunity (PDU).

To minimize latency contribution from the Bluetooth implementation, the Controller in both the HID Host and the HID Device should send an SDU received from its peer device to its Host as soon as the PDU carrying the SDU is received.

If the Controllers behave differently from what is described in the above two paragraphs, then the latency contribution from the Link Layer can be determined by the Transport Latency calculated by the Link Layer. The behavior described in the two paragraphs above does not affect the Controller's calculation of Transport Latency as described in [2] Volume 6, Part G, Section 3.2.2. The Transport Latency calculated by the Controller is not used by the application layer for a CIS that carries HID ISO packets. Figure 5.2 shows an adaptation of Figure 3.2 in [2] Volume 6, Part G, Section 3.2.2 to illustrate the behavior described in the above two paragraphs. Figure 5.2 uses black color for semantics copied from [2] with FT=1. Figure 5.2 uses red color for semantics used to describe SDUs and PDUs with the SDU interval identical to the ISO subinterval. Figure 5.2 uses green color for semantics used to describe the optimal behavior for HID ISO.

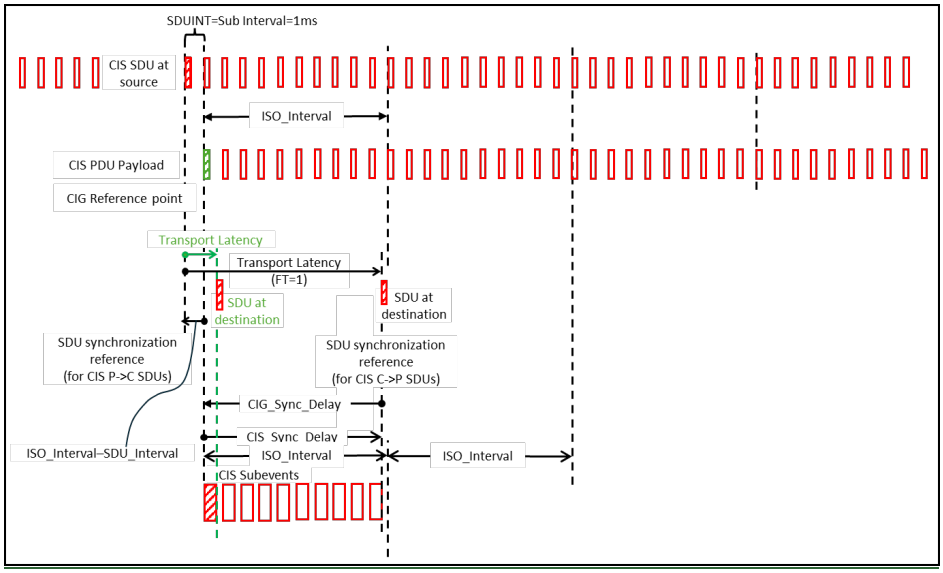

Figure 5.2 HID ISO compared to Figure 3.2 in Volume1 6, Part G, Section 3.2.2 in the Bluetooth Core Specification [2]

The Controller must follow the Bluetooth Core Specification requirements for ISOAL packet sequence numbers (see [2] Volume 6, Part G, Section 2), but the packet sequence number is not used for a CIS that carries HID ISO packets.

Note that an implementation of the HID ISO feature must synchronize generation of its data to the effective transport timing (i.e., the Host must send exactly one SDU, which can be empty, to the Controller each SDU interval) when using Unframed PDUs, see [2] Volume 6, Part G, Section 2.

Table 5.1 shows the requirements for report intervals.

Report interval	HID Host support	HID Device support
1 ms	O	O
1.25 ms	O	O
2 ms	O	O
2.5 ms	O	O
3 ms	O	O
3.75 ms	O	O
4 ms	O	O
5 ms	C.1	M
7.5 ms	C.1	M

Table 5.3: Report interval requirements

C.1: Mandatory to support at least one of 5 ms and 7.5 ms.

Appendix C shows recommended ISO parameters for each report interval setting, and the range of Max_Transport_Latency that can be used to constrain a generic Controller to achieve those settings.

5.4 HID ISO packet structure

Zero or more HID ISO packets may be sent in a single SDU over LE Isochronous Channels. A HID ISO packet can contain either a HID report or a Confirmation. Each HID ISO packet that contains a HID report shall use the format defined in Table 5.2. Each HID ISO packet that contains a Confirmation shall use the format defined in Table 5.3.

Field	Size	Value
Length	1 octet	The length of the Report field. The range is 1 to 255.
Sequence Number	1 octet	Sequence Number that shall be individually calculated and stored for each report (i.e., for each unique Report ID and HID report type combination) sent over LE Isochronous Channels. See Section 5.6 for details on Sequence Number handling. The range is 0 to 255.
Report ID	1 octet	For reports that do not contain a Report ID, this field shall be set to a value of 0. Otherwise, this field shall be set to equal the Report ID from the original report.
Report	Length octets	HID Report. If the report contains Report ID, it shall be excluded.

Table 5.4: HID ISO packet structure for HID Reports

If the Length field value is set to a value of 0, as shown in Table 5.3, then the packet is a Confirmation to the receipt of a report. The receiving device can use this Confirmation to stop sending reports with the same Sequence Number as the one contained in the Confirmation to save power.

Field	Size	Value
Length	1 octet	0
Sequence Number	1 octet	Sequence Number (see Section 5.6) for the report being confirmed. The range is 0 to 255.
Report ID	1 octet	Report ID field for the report being confirmed.

Table 5.5: HID ISO packet structure for Confirmation

5.5 HID ISO Protocol

The HID ISO Protocol is defined for transporting HID Reports over LE Isochronous Channels. This protocol provides the following capabilities:

- Redundancy – enables retransmission of the same packet with an optional confirmation to avoid unnecessary retransmission.
- Multiple reports per SDU – optionally provides the ability to include multiple reports in a single SDU to enable retransmission of packets concurrently with transmitting new packets.

A HID Host that supports the HID ISO feature shall support all the above capabilities.

The HID Device may support some of the above capabilities, and the HID Device shall indicate the support for Repetition (multiple reports per SDU) and Confirmation by setting the corresponding bits in the Additional Info subfield of the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic.

When the HID Host is instructed to enter hybrid mode by a higher layer, the higher layer can include requirements or recommendations for using Repetition or Confirmation. The HID Host should enable Repetition and Confirmation when supported by the HID Device in accordance with the instructions from the higher layer. If there are no recommendations or requirements from the higher layer, then the HID Host should enable Repetitions and Confirmation if supported by the HID Device.

It is up to the implementer of the device transmitting each report to use these features to provide a level of reliability that is adequate for the type of data contained in the report. The following report types are defined to provide guidance on how these features should be used.

ABSOLUTE: The Absolute report type is intended for reports that are more “absolute” in nature. Such reports contain data that represent the current state of an input mechanism, independent of any previous reports to be interpreted by the receiving side. Such reports often remain the same from one transmission to the next. For example, a report containing the status of a momentary push button or the position of a 2-position switch can be interpreted without knowledge of the values of previous reports.

RELATIVE: The Relative report type is intended for reports that are more “relative” in nature. Such reports contain data that are taken together with the values of previous reports to determine or derive another value. For example, the X and Y delta reports for a mouse or other pointing device are summed with previous values to determine the current X and Y coordinates of an on-screen pointer. For such reports, the loss of any single report can have a negative impact on user experience. Because of the nature of Bluetooth transmissions, any single transmission has some probability of being lost because of interference or multipath effects. The frequency hopping mechanism provides frequency diversity; therefore, if a packet is lost on one frequency, then the next transmission will occur on a different frequency on the same link. The existing retransmission (ARQ) schemes used at the Link Layer of Bluetooth LE would introduce too much latency because the receiver must send a negative acknowledgment and the original transmitter must retransmit the lost transmission, as required by Volume 6, Part B, Section 4.5.9 in [2]. To avoid this latency, a simple report repetition scheme is defined.

Some reports can contain both types of data. For example, a mouse report may contain X and Y delta data, which are considered relative, but also buttons, which are absolute. Such reports should be treated as Relative reports.

Reports carrying mouse X and Y delta data should be treated as Relative reports, and repetition should be used when these are carried over the LE Isochronous Channels transport.

5.5.1 Power saving confirmation of reception

When the Confirmation bit in the Additional Info subfield of the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic is set and the HID Host or HID Device receives a HID ISO packet, the receiving device shall send a Confirmation with the Sequence Number and the Report ID values equal to values of the same fields in the received HID ISO packet.

When the Confirmation bit in the Additional Info subfield of the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic is set and the HID Host or HID Device receives a Confirmation, the device receiving the Confirmation may stop sending the HID ISO packet identified by the Sequence Number and Report ID in the Confirmation.

Note that the receiving device can still receive additional duplicates of a report, even if it has sent the Confirmation, because the sending device may not have received the Confirmation, could have buffered multiple copies for sending before receiving the Confirmation, or may have decided not to stop sending the report.

5.6 Sequence Number handling

The Sequence Number is maintained independently for each Report ID that is enabled to use the LE Isochronous Channels transport.

Section 5.6.1 and Section 5.6.2 specify how the Sequence Number field should be generated for transmission and interpreted upon receipt.

5.6.1 Sequence Number generation

Upon the establishment of a CIS connection, the transmitter shall initialize the Sequence Number to a value of 0 for each report with a given Report ID.

Whenever the content of a report changes, the Sequence Number shall be incremented after creating the HID ISO packet. The transmitter also may increment the Sequence Number when the content does not change if the content of the report represents a distinct user action from the report with the previous Sequence Number. For example, a mouse might produce a report containing deltaX = 5 followed by another report containing deltaX = 5. While the content is the same, the two reports together represent a user input that caused a total deltaX change of 10.

When the Repetition bit in the Additional Info subfield of the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic is set, the sending device may include a given Report ID in an SDU with its current Sequence Number along with one or more previous values of that Report ID with previous Sequence Numbers. The reports shall be included in the SDU in order of increasing Sequence Number. The number of reports with the same Report ID in an SDU shall be less than or equal to 8. The limitations for the maximum SDU sizes specified in the HID ISO Properties characteristic can limit the number to less than 8. The maximum SDU sizes are defined by the implementer of the HID Device, considering the air-time available for HID ISO packets at the minimum report rate supported by the HID Device.

Table 5.4 shows an example with three repetitions (“r” is a report with a given Report ID, and the number following “r” represents the Sequence Number).

SDU number	Packet(s) in SDU	Packet sent to upper layer
0	r0	r0
1	r0, r1	r1
2	r0, r1, r2	r2
3	r1, r2, r3	r3
4	r2, r3, r4	r4
...	...	...

Table 5.6: Example of multiple packets per SDU when using repetitions

5.6.2 Sequence Number handling upon receipt

Upon receipt of an SDU over the LE Isochronous Channels transport, the receiver shall process the contents of the SDU as described in this section.

The receiving device shall process all packets in the SDU in sequence. The processing of each HID ISO packet is independent from the SDU the packet arrives in. Only the arrival sequence of the HID ISO packets impacts the packet processing.

If the Length field in a packet is set to a value of 0, then the packet is a Confirmation of a packet previously sent from that device. The device that received the Confirmation may stop sending further copies of the packet identified in the report (to save power).

If the Length field in a packet is set to a value greater than 0, then the packet contains a HID Report. In this case, the receiving device shall process the Report ID and Sequence Number fields as follows:

- If the receiving device has previously received reports with the Report ID in this connection and (previously stored Sequence Number – Sequence Number) *mod* 256 is less than or equal to 7 (because the Sequence Number is in the past), then the receiving device shall ignore this packet.
- Otherwise, the receiving device shall deliver the HID Report to a higher layer and store the Sequence Number.

If the Report ID is 0, then the HID Report sent to the higher layer shall be the Report field of the packet.

If the Report ID is not 0, then the HID Report sent to the higher layer shall be the Report field prepended with the Report ID field of the packet.

6 HID ISO Service

The HID ISO Service defines one characteristic to describe the ISO-related properties of the HID Device, and one characteristic to configure the HID ISO behavior and the state changes between the Default Operation mode and Hybrid Operation mode.

6.1 Service dependencies

The HID ISO Service does not depend on any other services.

6.2 Attribute Protocol Application error codes

The HID ISO Service defines the Attribute Protocol Application error codes listed in Table 6.1.

Name	Error Code	Description
Opcode outside range	0x81	Opcode is in the RFU range
Device already in requested state	0x82	The HID host has requested the HID Device to change to the state it is already in
Unsupported feature	0x83	Request contains settings that are not supported according to the Features field of the HID ISO Properties characteristic

Table 6.7: Attribute Protocol Application error codes defined by the HID ISO Service

6.3 GATT sub-procedure requirements

Requirements in this section represent a minimum set of requirements for a Server. Other GATT sub-procedures may be used if supported by both the Client and Server.

Table 6.2 summarizes additional GATT sub-procedure requirements beyond those required by all GATT Servers.

GATT sub-procedure	Requirements
Write Characteristic Value	M
Indications	C.1

Table 6.8: GATT sub-procedure requirements

C.1: Mandatory if the Device Mode Change Supported feature is set, otherwise optional.

6.4 Declaration

The HID ISO Service shall be instantiated as a «Primary Service».

Only one instance of the HID ISO Service shall be allowed on a Server.

Commented [SIG45]: 27651

The service UUID shall be set to «HID ISO Service» as defined in [7].

6.5 Service characteristics

This section defines the characteristic requirements. Where a characteristic can be indicated, a Client Characteristic Configuration descriptor must be included in that characteristic as required by [2].

The characteristics defined in this section are using the conventions described in Section 2 of the GATT Specification Supplement [10].

Characteristic Name	Requirement	Mandatory Properties	Optional Properties	Security Permissions
HID ISO Properties (Section 6.5.1)	M	Read	None	None
LE HID Operation Mode (Section 6.5.2)	M	Write	Indication	None

Table 6.9: HID ISO Service characteristics

6.5.1 HID ISO Properties

The HID ISO Properties characteristic is used to show the device's HID ISO features, supported report intervals for HID ISO, and mapping of reports that will use the LE Isochronous Channels in the Hybrid Operation mode. The value of the HID ISO Properties shall be static during a connection.

6.5.1.1 Characteristic format

The structure of this characteristic is defined in Table 6.4.

Field	Data Type	Size (in octets)	Description
Features	boolean[8]	1	Supported HID ISO features of the HID Device. See Section 6.5.1.1.1.
Supported Report Intervals	boolean[16]	2	Supported report intervals for the HID Device. See Section 6.5.1.1.2.
Max SDU Size for Input Reports	uint8	1	Maximum SDU size the HID Device can use to send ISO data to the HID Host. Maximized robustness with no impact on latency. The sum of the longest Input Report length and the HID ISO protocol header multiplied by the maximum number of repetitions.
Preferred SDU Size for Input Reports	uint8	1	Preferred SDU size the HID Device will use to send ISO data to the HID Host. Most use cases experience no or minor performance impact. The sum of the most critical Input Report length and the HID ISO protocol header multiplied by the maximum number of repetitions.

Field	Data Type	Size (in octets)	Description
Max SDU Size for Output Reports	uint8	1	Maximum SDU size the HID Host can use to send ISO data to the HID Device. Maximized robustness with no impact on latency. The sum of the longest Output Report length and the HID ISO protocol header multiplied by the maximum number of repetitions.
Preferred SDU Size for Output Reports	uint8	1	Preferred SDU size the HID Host can use to send ISO data to the HID Device. Most use cases experience no or minor performance impact. The sum of the most critical Output Report length and the HID ISO protocol header multiplied by the maximum number of repetitions.
Hybrid Mode ISO Reports	struct[1-6]	2 to 12	Array of structs describing each Report Type and Report ID combination that the HID Device may use for transmission over LE Isochronous Channels in the Hybrid Operation mode. See Section 6.5.1.1.3.

Table 6.10: Characteristic format

6.5.1.1.1 Features field

The values of the Features field are defined in Table 6.5.

Bit	Description
0	Device Mode Change Supported
1 to 7	RFU

Table 6.11: Features field

6.5.1.1.2 Supported Report Intervals field

The values of the Supported Report Intervals field are defined in Table 6.6.

Bit	Description
0	1 ms
1	2 ms
2	3 ms
3	4 ms
4	5 ms
5	1.25 ms
6	2.5 ms

Bit	Description
7	3.75 ms
8	7.5 ms
10 to 15	RFU

Table 6.12: Supported Report Intervals field

6.5.1.1.3 Hybrid Mode ISO Reports field

Each struct in the Hybrid Mode ISO Reports field is defined in Table 6.7.

Field	Data Type	Size (in octets)	Description
Report ID	uint8	1	Report ID for the Input or Output report.
Additional Info	boolean[8]	1	See Section 6.5.1.1.3.1

Table 6.13: Hybrid Mode ISO Reports field

6.5.1.1.3.1 Additional Info sub-field

The individual bits in the Additional Info sub-field are defined in Table 6.8

Bit	Description
0	Report Type When the value is 0, the report is an Input Report. When the value is 1, the report is an Output Report.
1	Confirmation Supported
2	Repetition Supported
3 to 7	RFU

Table 6.14: Additional Info sub-field

6.5.1.2 Characteristic behavior

The HID ISO Properties characteristic returns its associated value when it is read by the HID Host.

6.5.2 LE HID Operation Mode

The LE HID Operation Mode characteristic is used to switch operation modes between Default Operation mode and Hybrid Operation mode.

6.5.2.1 Characteristic format

The structure of this characteristic is defined in Table 6.9.

Field	Data Type	Size (in octets)	Description
Opcode	uint8	1	Select Hybrid Operation Mode or Select Default Operation Mode. See Section 6.5.2.1.1.
Parameters	struct	0 to 17	Parameters contents depend on the Opcode. See Section 6.5.2.1.1.

Table 6.15: LE HID Operation Mode characteristic format

6.5.2.1.1 Opcode field

The values for the Opcode field when initiating a procedure are shown in Table 6.10.

Opcode	Parameters	Description
0x01	As defined in Section 6.5.2.1.2.	Select Hybrid Operation Mode.
0x02	None	Select Default Operation Mode.
All other values	RFU	RFU

Table 6.16: Opcode field and Parameters field

6.5.2.1.2 Parameters field

The content of the Parameters field (when Opcode is Select Hybrid Operation Mode) is shown in Table 6.11.

Field	Data Type	Size (in octets)	Description
CIG ID	uint8	1	CIG ID for the CIG created by the HID Host.
CIS ID	uint8	1	CIS ID for the CIS created by the HID Host for the HID Reports.
Report Interval	boolean[16]	2	Report interval selection. Encoded identically to the Supported Report Intervals field of the HID ISO Properties characteristic (see Section 6.5.1.1.2). Only one bit is set to a value of 1; all other bits are set to a value of 0.
Current SDU Size for Input Reports	uint8	1	Maximum SDU Size for SDUs from the HID Device to the HID Host for the Hybrid Mode session started by this command.

Commented [SIG46]: 27651

Field	Data Type	Size (in octets)	Description
Current SDU Size for Output Reports	uint8	1	Maximum SDU Size for SDUs from the HID Host to the HID Device for the Hybrid Mode session started by this command.
Hybrid Mode ISO Reports Enable	struct[1-2]	1 to 2	Array of 8-bit structs containing indices into the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic and settings for Confirmation and Repetition flags for the Reports enabled for Hybrid Operation Mode. See Section 6.5.2.1.2.1.

Table 6.17: Parameters field

6.5.2.1.2.1 Hybrid Mode ISO Reports Enable sub-field

The fields of the Hybrid Mode ISO Reports Enable sub-field are defined in Table 6.12.

Field	Data Type	Size (in bits)	Description
Report Info Index	uint3	3	Index into the Hybrid Mode ISO Reports field of the HID ISO Properties characteristic. The Report ID and Report Type to be enabled over ISO in Hybrid Mode. The first array element has index 0.
RFU	boolean[3]	1	Reserved for future use.
Confirmation Enable	boolean	1	Enable Confirmation for the Report ID and Report Type referenced by the Report Info Index field.
Repetition Enable	boolean	1	Enable Repetition for the Report ID and Report Type referenced by the Report Info Index field.

Table 6.18: Hybrid Mode ISO Reports Enable sub-field

6.5.2.2 Characteristic behavior

The HID Device behavior when writing or indicating the LE HID Operation Mode characteristic is described in Section 5.2.

Commented [SIG47]: 14917

~~6~~7 Security ~~Considerations~~ requirements

This section describes the security considerations for a HID Device and HID Host.

~~6.1~~7.1 Device security ~~Considerations~~requirements

The HID Device, which must be a Peripheral as per Section 2.4, shall be in the Bondable mode as ~~defined in [2]use LE Security Mode 1 and either Security Level 2 or~~ Volume 3~~.~~, Part C, Section 9.4.3.

~~All supported~~ HID Service characteristics ~~specified by the HID Service~~ shall ~~be set to Security Mode 1 and either Security Level 2 or 3.~~

~~HID Devices shall bond and use LE Security Mode 1, Security Level 2 or 3, both of which~~ require an encrypted link~~. Encryption is used to verify that a bond still exists and is valid.~~ for reading, writing, and notification.

The HID Device should use the ~~SM Slave~~ Peripheral Security Request, as defined in [2] Volume 3, Part H, Section 2.4.6, procedure to inform the HID Host of its security requirements.

All supported characteristics specified by the Device Information Service, Scan Parameters Service, and Battery Service should be set to the same LE Security Mode and the same Security Level as the characteristics in the HID Service.

~~6.2~~7.2 Host security ~~Considerations~~requirements

The HID Host, which must be a Central as per Section 2.4, shall ~~bond~~perform the Bonding procedure with the HID Device, as defined in [2]~~.~~ Volume 3, Part C, Section 9.4.4.

The HID Host ~~shall support LE Security Mode 1 and Security Level 2 and optionally Security Level 3.~~

~~The HID Host shall accept any valid LE Security Mode and Security Level combination requested by~~should encrypt the ~~HID Device.~~link as early as possible after reconnection.

The HID Host shall only initiate an encryption key refresh on receipt of a ~~SM Slave~~ Peripheral Security Request, as defined in [2] Volume 3, Part H, Section 2.4.6, from the HID Device.

~~11 Appendix A~~

Appendix A Connection behavior Normally Connectable

Table A.1 details the Host and Device connection behavior as a function of NormallyConnectable bit of the HID Information characteristic.

Normally Connectable	LE reconnection requirements	Comments
FALSE	Device: - if data to transmit: high duty-cycle advertising for ~~5s~~ 5 s - if idle: radio off Host: - low duty-cycle scanning	Most common configuration
TRUE	Device: - if data to transmit: high duty-cycle advertising for ~~5s~~ 5 s - if idle: low duty-cycle advertising Host: - if data to transmit: high duty-cycle scanning for ~~5s~~ 5 s - if idle: low duty-cycle scanning	In this case, it is preferred to keep the LE HID connection active always.

Appendix C Link Layer parameters

C.1 Recommended ISO parameters

Table C.1 shows the recommended ISO parameters and the range of Max_Transport_Latency that can be used to constrain a generic Controller to the ISO_Interval for each report interval setting. The NSE(=BN) and FT=1 are constrained by the selection of SDU interval (i.e., the Controller must select an ISO_Interval that is an integer multiple of the SDU interval for unframed and unfragmented ISO data).

Report interval	ISO_Interval	NSE (=BN)	FT
1 ms	5 ms	5	1
	10 ms	10	1
	15 ms	15	1
1.25 ms	5 ms	4	1
	7.5 ms	6	1
	10 ms	8	1
	15 ms	12	1
2 ms	10 ms	5	1
	20 ms	10	1
2.5 ms	7.5 ms	3	1
	10 ms	4	1
	15 ms	6	1
	20 ms	8	1
3 ms	15 ms	5	1
3.75 ms	7.5 ms	2	1
	15 ms	4	1

Report interval	ISO_Interval	NSE (=BN)	FT
4 ms	20 ms	5	1
5 ms	5 ms	1	1
	10 ms	2	1
	20 ms	4	1
7.5 ms	7.5 ms	1	1

Table C.1: Recommended ISO parameters.

Note that using a Report Interval of 3 ms, 3.75 ms, or 4 ms with a Controller that is not using the configurations and behaviors recommended for minimum latency contribution in Section 5.3 can cause the Controller to select an ISO interval that is greater than or equal to 15 ms or to use framed PDUs. This will result in a significant increase in the latency contribution from Bluetooth Link Layer protocols.

C.2 Example timing of 1 ms report interval

To check the implementation possibility, a timing calculation of having a 1 ms report interval is explained. The GAP Peripheral role here corresponds to the HID Device role, and the GAP Central role corresponds to the HID Host role.

In this example, a 1 ms report interval is equivalent to a 1 ms Sub_Interval in the LE ISO channel.

The HID ISO data traffic is assumed to be from the Peripheral to the Central only. The Central sends the Peripheral a null (empty) packet. The size of a null packet is 11 octets: Preamble (2 octets) + Access Address (4 octets) + Header (2 octets) + CRC (3 octets). The null packet timing is 44 µs at 2M PHY.

Assuming a HID payload for gaming device data, which is 16 octets long, the size of the HID report packet is 31 octets long: Preamble (2 octets) + Access Address (4 octets) + Header (2 octets) + Payload (16 octets) + CRC (3 octets) + MIC (4 octets). The HID report packet timing is 124 µs at 2M PHY.

If the data is ready at the Sub_Interval, then the Peripheral will send the HID report packet with the data to the Central. If the data is not ready at the Sub_Interval, then the Peripheral will send an empty packet to the Central.

For a HID data size of 16 octets, the minimum SE_Length (Sub Event Length, per Volume 6, Part B, Section 4.5.13.1 of [2]) is 468 µs, where T_IFS (Inter Frame Space, per Volume 6, Part B, Section 4.1.1 of [2]) and T_MSS (Minimum Sub Event Space, per Volume 6, Part B, Section 4.1.3 of [2]) are both 150 µs.

This timing is illustrated in Figure C.1. BN (Burst Number) and NSE (Number of Sub Events) are both equal to 5 and FT (Flush Timeout) is equal to 1.

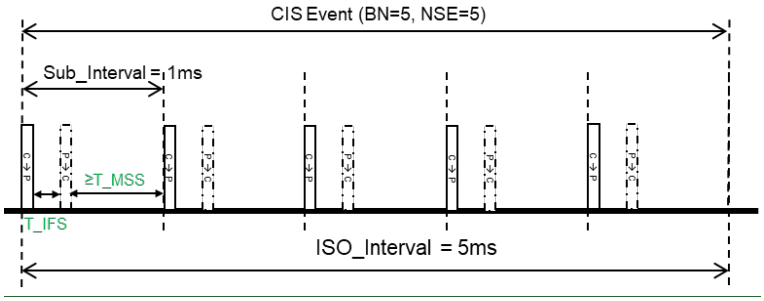

Figure C.1: Timing diagram of 1 ms report interval

ACL packets for the ACL associated with the ISO channel can be scheduled in an empty space after T_MSS of any sub-event. Periodic ACL packet transfer is necessary to maintain ISO connection and can be used to exchange Link Layer control packets and low bandwidth data.

For a HID Data size of 16 octets, the SE_Length of 468 µs leaves 532 µs for the ACL event. The ACL event can be used, for example, for a GATT transaction with the default GATT MTU or a Link Layer control transaction. Figure C.2 shows an ACL event with a 27 octet PDU in the Central to Peripheral direction, and a shorter, 9 octet PDU in the Peripheral to Central direction.

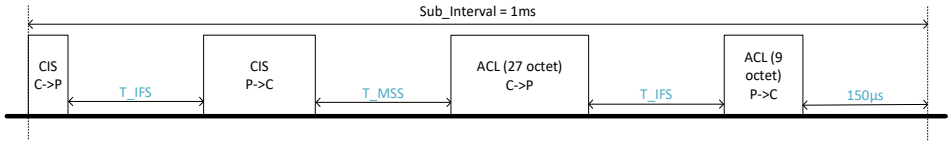

Figure C.2: One sub-interval with ACL event

If the sum of the two ACL PDUs exceed 36 octets (the 4 octet MIC for a non-empty PDU is included in this number), then the behavior will be defined by Controller implementation. Some Controllers will drop the following ISO sub-event, with minimal impact to the HID ISO data stream (the probability of the lost ISO event carrying an empty or redundant payload is high). Other Controllers will drop the ACL event. Dropping every ACL event can lead to link loss.

An application can use a 1.25 ms SDU_Interval for an additional 29 octets of data (either ISO or ACL) if more bandwidth needs to be available for ACL traffic or to have longer HID ISO payloads. For example, an application that uses the maximum HID ISO data size (48 octets) can support 33 octets of ACL data when the SDU interval is 1.25 ms.

If the HID ISO payloads are longer or the ACL data can be longer than the default MTU size, then the application may use the Frame Space Update feature to reduce the 150 µs waits between packets.
